

## 12. Testing Implicit Hypotheses I

### Implicit Hypothesis Testing and the Delta Method

#### Deriving a Test for Implicit Hypotheses

In the next few problems, we derive a general method for testing hypotheses of the form

$$H_0 : g(\theta^*) = 0$$

$$H_1 : g(\theta^*) \neq 0$$

where  $g$  is a function of an unknown parameter  $\theta^*$ . We refer to such hypotheses as **implicit** since  $\theta^*$  is not isolated in the equations defining the null and alternative hypotheses.

Let's suppose that

- $\theta^* \in \mathbb{R}^d$  is unknown.
- $g : \mathbb{R}^d \rightarrow \mathbb{R}^k$  has is continuously differentiable (*i.e.*, the gradient  $\nabla g$  is continuous).
- $\hat{\theta}_n$  is an asymptotically normal estimator; *i.e.*,

$$\sqrt{n}(\hat{\theta}_n - \theta^*) \xrightarrow[n \rightarrow \infty]{(d)} \mathcal{N}(\mathbf{0}, \Sigma(\theta^*)), \quad \Sigma(\theta^*) \in \mathbb{R}^{d \times d}.$$

1/1 point (graded)  
Recall that  $\hat{\theta}_n$  is an asymptotically normal estimator; *i.e.*,

$$\sqrt{n} \left( \hat{\theta}_n - \theta^* \right) \xrightarrow[n \rightarrow \infty]{(d)} \mathcal{N} \left( \mathbf{0}, \Sigma \left( \theta^* \right) \right), \quad \Sigma \left( \theta^* \right) \in \mathbb{R}^{d \times d}.$$

This implies, by the Delta method, that  $g \left( \hat{\theta}_n \right)$  is also asymptotically normal; *i.e.*,

$$\sqrt{n} \left( g \left( \hat{\theta}_n \right) - g \left( \theta^* \right) \right) \xrightarrow[n \rightarrow \infty]{(d)} \mathcal{N} \left( \mathbf{0}, \Gamma \left( \theta^* \right) \right), \quad \Gamma \left( \theta^* \right) \in \mathbb{R}^{k \times k}.$$

Which of the following is  $\Gamma \left( \theta^* \right)$ , the asymptotic covariance matrix?

- ☐  $\nabla g(\theta^*)^T \Sigma(\theta^*)$
- ☒  $\nabla g(\theta^*)^T \Sigma(\theta^*) \nabla g(\theta^*) \quad \square$
- ☐  $\nabla g(\theta^*) \Sigma(\theta^*) \nabla g(\theta^*)^T$
- ☐  $\nabla g(\theta^*)^{-1} \Sigma(\theta^*) (\nabla g(\theta^*)^{-1})^T$

**Solution:**

The Delta method states that if

$$\sqrt{n} \left( \hat{\theta}_n - \theta^* \right) \xrightarrow[n \rightarrow \infty]{(d)} \mathcal{N} \left( \mathbf{0}, \Sigma \left( \theta^* \right) \right),$$

then

$$\sqrt{n} \left( g \left( \hat{\theta}_n \right) - g \left( \theta^* \right) \right) \xrightarrow[n \rightarrow \infty]{(d)} \mathcal{N} \left( \mathbf{0}, \nabla g(\theta^*)^T \Sigma \left( \theta^* \right) \nabla g \left( \theta^* \right) \right) \in \mathbb{R}^{k \times k}$$

provided that  $g$  is continuously differentiable. Hence the second answer choice  $\nabla g(\theta^*)^T \Sigma \left( \theta^* \right) \nabla g \left( \theta^* \right)$  is correct.

We can easily see that some of the other given answer choices are incorrect by inspecting the dimensions of the matrices involved. Note that  $\nabla g$  is a  $d \times k$  matrix and  $\Sigma \left( \theta^* \right)$  is a  $d \times d$  matrix.

- The matrix product  $\nabla g(\theta^*)^T \Sigma \left( \theta^* \right)$  will exist, but it is not a square matrix unless  $k = d$ . Hence, this cannot be a covariance matrix, so the first answer choice is incorrect.
- The matrix product given by  $\nabla g \left( \theta^* \right) \Sigma \left( \theta^* \right) \nabla g(\theta^*)^T$  will not exist if  $k \neq d$ , so the third answer choice is incorrect.
- The fourth answer choice is incorrect. Since  $\nabla g$  is a  $d \times k$  matrix, it will not be invertible if  $d \neq k$ . Hence, the matrix product  $\nabla g(\theta^*)^{-1} \Sigma \left( \theta^* \right) \nabla g(\theta^*)^{-T}$  will not exist in general.

Testing Implicit Hypotheses II: Renormalizing

As above, by the Delta method, we have that

$$\sqrt{n}\left(g\left(\hat{\theta}_n\right)-g\left(\theta^*\right)\right) \stackrel{(d)}{\underset{n \rightarrow \infty}{\longrightarrow}} \mathcal{N}\left(\mathbf{0}, \Gamma\left(\theta^*\right)\right),$$

for some matrix  $\Gamma\left(\theta^*\right) \in \mathbb{R}^{k \times k}$ .

For some real number  $x$ ,

$$\sqrt{n} \Gamma\left(\theta^*\right)^x\left(g\left(\hat{\theta}_n\right)-g\left(\theta^*\right)\right) \stackrel{(d)}{\underset{n \rightarrow \infty}{\longrightarrow}} \mathcal{N}\left(\mathbf{0}, I_k\right) .$$

(You are allowed to assume  $\Gamma\left(\theta^*\right)^x$  exists for any  $x \in \mathbb{R}$ .)

What is  $x$ ?

-1/2

Answer: -0.5

Solution:

By the properties of multivariate Gaussians, if  $\mathbf{Z} \sim \mathcal{N}\left(\mathbf{0}, \Gamma\left(\theta^*\right)\right)$ , then

$$\Gamma\left(\theta^*\right)^{-1 / 2} \mathbf{Z} \sim \mathcal{N}\left(\mathbf{0}, I_k\right)$$

provided that  $\Gamma\left(\theta^*\right)^{-1 / 2}$  exists. We proved this property in general in the problem "Review: Manipulating Multivariate Gaussians" in the vertical "Introduction to Wald's Test" from this lecture.

**Remark:** For a square matrix  $M$ , we are guaranteed that  $M^{-1 / 2}$  exists if  $M$  is positive-definite. In particular, since  $\Gamma\left(\theta^*\right)$  is a covariance matrix, it is guaranteed to be positive semidefinite. So then  $\Gamma\left(\theta^*\right)^{-1 / 2}$  exists if and only if  $\Gamma\left(\theta^*\right)$  is invertible. Moreover, by the previous problem,

$$\Gamma\left(\theta^*\right)=\nabla g\left(\theta^*\right)^T \Sigma\left(\theta^*\right) \nabla g\left(\theta^*\right) .$$

Hence,  $\Gamma\left(\theta^*\right)$  is invertible if  $\Sigma$  is invertible and  $\nabla g\left(\theta^*\right)$  is rank  $k$ .
