How do neurons connect to form networks?

They use synapses!

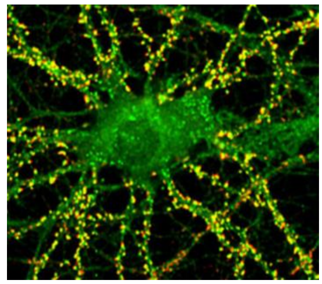

Image Source: Wikimedia Commons

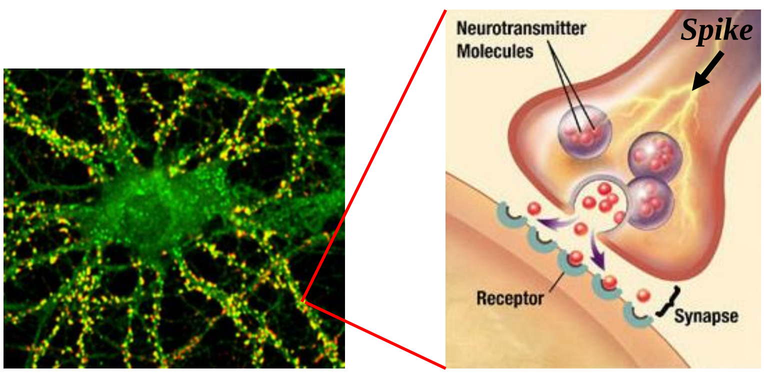
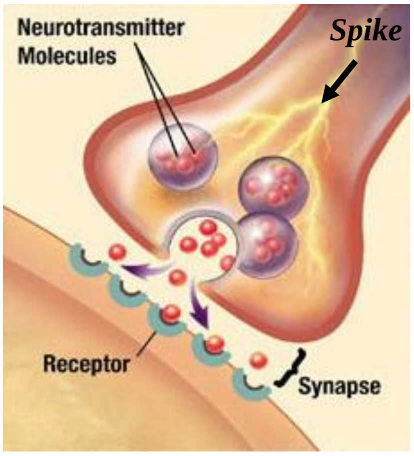
What do synapses do?



Increase or decrease postsynaptic membrane potential

Image Source: Wikimedia Commons

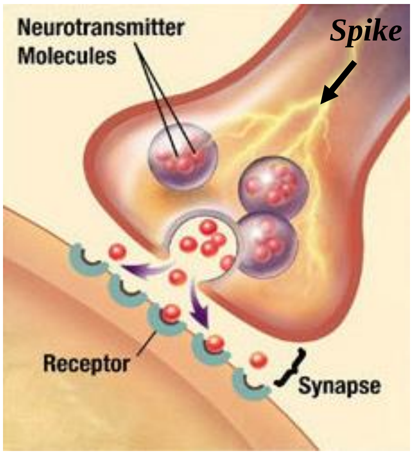
An Excitatory Synapse



Input spike →
Neurotransmitter release
(e.g., Glutamate) →
Binds to receptors →
Ion channels open →
positive ions (e.g. Na+)
enter cell →
Depolarization
(increases local
membrane potential)

Image Source: Wikimedia Commons

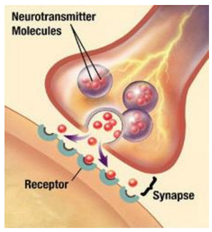
An Inhibitory Synapse

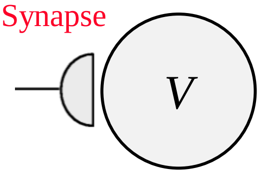


Input spike →
Neurotransmitter
release (e.g., GABA)
→ Binds to receptors
→ Ion channels open
→ positive ions (e.g.,
K+) leave cell →
Hyperpolarization
(decreases local
membrane potential)

Image Source: Wikimedia Commons

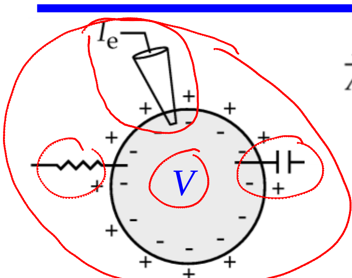
We want a *computational* model of the effects of a synapse on the membrane potential V

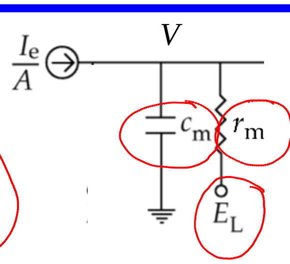




How do we do this?

Flashback — RC Circuit Model of the Membrane





$c_m \approx 10$ nF/mm^2

$r_m \approx 1$ MΩ mm^2

$C_m = c_m A$

$R_m = r_m / A$

$E_L = -70$ mV

$q = C_m V$

$\frac{dq}{dt} = i = C_m \frac{dV}{dt}$

$$c_m \frac{dV}{dt} = -\frac{(V - E_L)}{r_m} + \frac{I_e}{A}$$

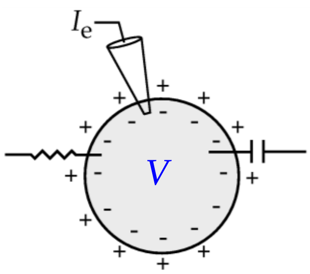
or equivalently:

$\tau_m = r_m c_m = R_m C_m$ is the membrane time constant

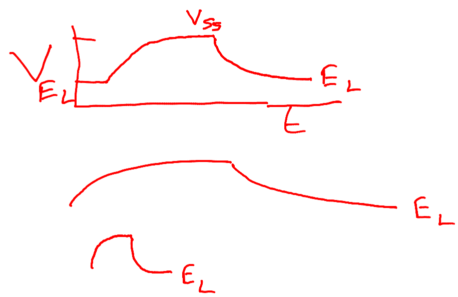
$$\boxed{\tau_m \frac{dV}{dt} = -(V - E_L) + I_e R_m}$$

Image Source: Dayan & Abbott textbook

What is this equation really saying?



$$\boxed{\tau_m \frac{dV}{dt} = -(V - E_L) + I_e R_m} \rightarrow 0$$

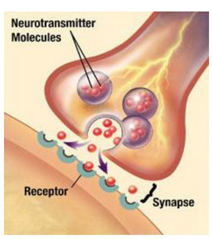


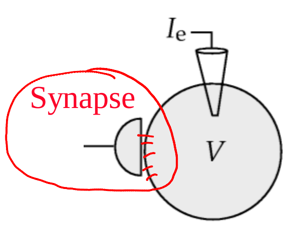
$0 = -(V - E_L) + I_e R_m$

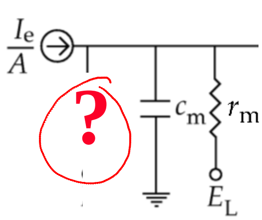
$V_{ss} = E_L + I_e R_m$

Image Source: Dayan & Abbott textbook

How do we model the effects of a synapse on the membrane potential V ?

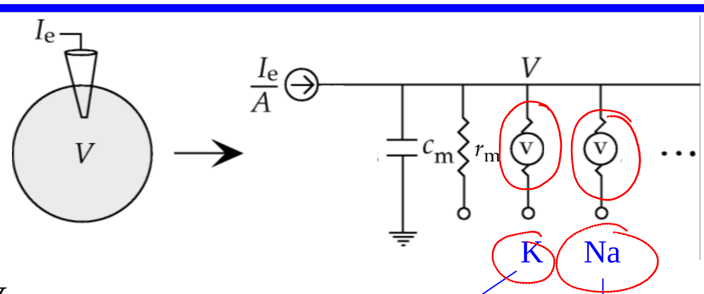






Hint!

Hodgkin-Huxley Model



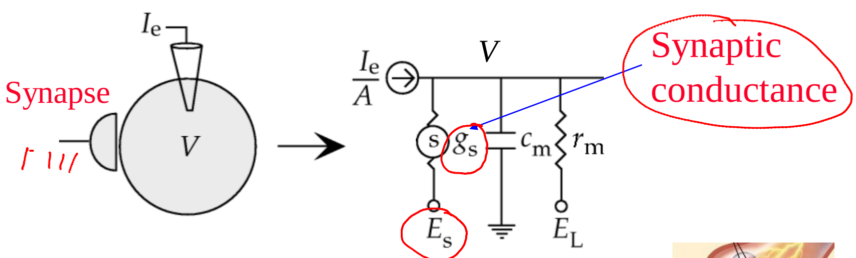
$$\tau_m \frac{dV}{dt} = -i_m r_m + I_e R_m$$

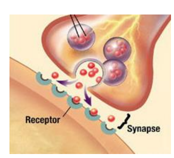
$$i_m = (1/r_m)(V - E_L) + g_{K,\max} n^4 (V - E_K) + g_{Na,\max} m^3 h (V - E_{Na})$$

E_L = -54 mV, E_K = -77 mV, E_{Na} = +50 mV

Image Source: Dayan & Abbott textbook

Modeling Synaptic Inputs



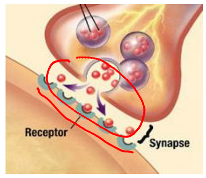


$$\tau_m \frac{dV}{dt} = -((V - E_L) + g_s (V - E_s) r_m) + I_e R_m$$

$g_s = g_{s,\max} P_{rel} P_s$ ← Probability of postsynaptic channel opening (= fraction of channels opened)

Probability of transmitter release given an input spike

Basic Synapse Model



$g_s = g_{s,\max} P_{rel} P_s$

- Assume $P_{rel} = 1$
- Model the effect of a single spike input on P_s
- Kinetic Model of postsynaptic channels:

fraction of channels opened

$$\text{Closed} \underset{\beta_s}{\overset{\alpha_s}{\rightleftharpoons}} \text{Open}$$

$$\frac{dP_s}{dt} = \alpha_s (1 - P_s) - \beta_s P_s$$

Opening rate

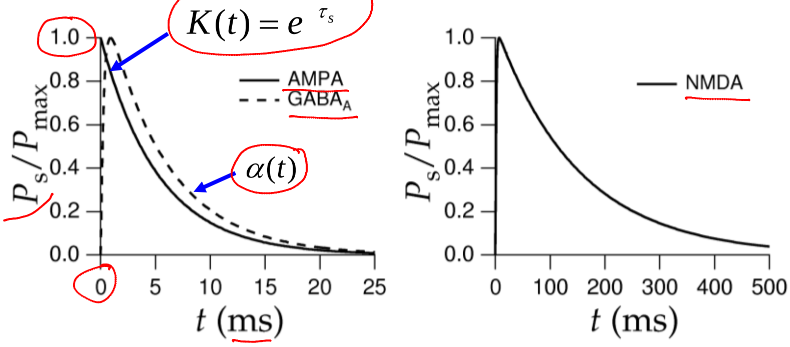
Fraction of channels closed

Closing rate

Fraction of channels open

What does P_s look like over time given a spike?

$$K(t) = e^{-\frac{t}{\tau_s}}$$



Exponential function gives reasonable fit for some synapses

Others can be fit using "Alpha" function:

$$\alpha(t) = \frac{t}{\tau_{peak}} \cdot e^{(1 - \frac{t}{\tau_{peak}})}$$

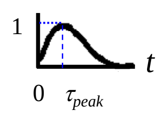


Image Source: Dayan & Abbott textbook

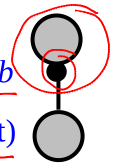
Linear Filter Model of a Synapse

Synapse b

Input Spike Train $\rho_b(t)$



$\rho_b(t) = \Sigma_i\, \delta(t\text{-}t_i)$ (t_i are the input spike times, δ = delta function)

Filter for synapse b = $K(t)$

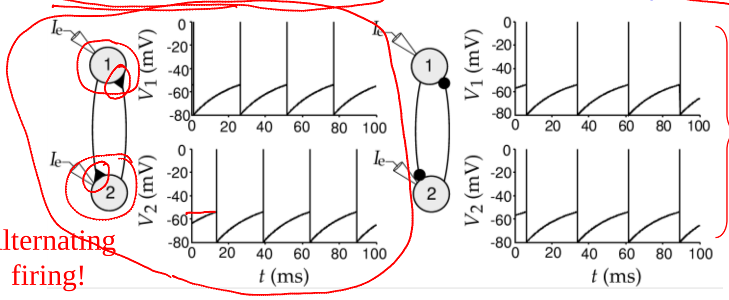
Synaptic conductance at b:

$$g_b(t) = g_{b,\max} \sum_{t_i<t} K(t - t_i)$$

$$= g_{b,\max} \int_{-\infty}^{t} K(t-\tau)\rho_b(\tau)d\tau$$

Example: Network of Integrate-and-Fire Neurons

Excitatory synapses (E_s = 0 mV)   Inhibitory synapses (E_s = -80 mV)



Alternating firing!

Synchrony!

Each neuron: $\tau_m \dfrac{dV}{dt} = -((V - E_L) - g_s(t)(V - E_s)r_m) + I_e R_m$

Synapses : Alpha function

$E_L = -70\text{ mV}$ $V_{thresh} = -54\text{ mV}$

$\tau_m = 20\text{ ms}$ $\tau_{peak} = 10\text{ ms}$ $I_e R_m = 25\text{ mV}$
