18.650 - Fundamentals of Statistics

3. Methods for estimation

Goals

In the kiss example, the estimator was **intuitively** the right thing to do: $\hat{p} = \bar{X}_n$.

In view of LLN, since $p=\mathbb{E}[X]$, we have \bar{X}_n so $\hat{p}\approx p$ for n large enough.

If the parameter is $\theta \neq \mathbb{E}[X]$? How do we perform?

- Maximum likelihood estimation: a generic approach with very good properties
- 2. Method of moments: a (fairly) generic and easy approach
- 3. M-estimators: a flexible approach, close to machine learning

Total variation distance

Let $(E,(\mathbb{P}_{\theta})_{\theta\in\Theta})$ be a statistical model associated with a sample of i.i.d. r.v. X_1,\ldots,X_n . Assume that there exists $\theta^*\in\Theta$ such that $X_1\sim\mathbb{P}_{\theta^*}\colon\theta^*$ is the **true** parameter.

Statistician's goal: given X_1,\ldots,X_n , find an estimator $\hat{\theta}=\hat{\theta}(X_1,\ldots,X_n)$ such that $\mathbb{P}_{\hat{\theta}}$ is close to \mathbb{P}_{θ^*} for the true parameter θ^* .

This means: $\left|\mathbb{P}_{\hat{\theta}}(A) - \mathbb{P}_{\theta^*}(A)\right|$ is small for all $A \subset E$.

Definition

The total variation distance between two probability measures \mathbb{P}_{θ} and $\mathbb{P}_{\theta'}$ is defined by

$$\mathsf{TV}(\mathbb{P}_{\theta}, \mathbb{P}_{\theta'}) = \max_{A \subset E} \Big| \mathbb{P}_{\theta}(A) - \mathbb{P}_{\theta'}(A) \Big|$$

Total variation distance between discrete measures

Assume that E is discrete (i.e., finite or countable). This includes Bernoulli, Binomial, Poisson, . . .

Therefore X has a PMF (probability mass function): $\mathbb{P}_{\theta}(X = x) = p_{\theta}(x)$ for all $x \in E$,

$$p_{\theta}(x) \ge 0 \ , \quad \sum_{x \in E} p_{\theta}(x) = 1 \ .$$

The total variation distance between \mathbb{P}_{θ} and $\mathbb{P}_{\theta'}$ is a simple function of the PMF's p_{θ} and $p_{\theta'}$:

$$\mathsf{TV}(\mathbb{P}_{\theta}, \mathbb{P}_{\theta'}) = \frac{1}{2} \sum_{x \in E} \left| p_{\theta}(x) - p_{\theta'}(x) \right|.$$

Total variation distance between continuous measures

Assume that E is continuous. This includes Gaussian, Exponential, \dots

Assume that X has a density $\mathbb{P}_{\theta}(X \in A) = \int_A f_{\theta}(x) dx$ for all $A \subset E$.

$$f_{\theta}(x) \ge 0, \quad \int_{E} f_{\theta}(x) dx = 1.$$

The total variation distance between \mathbb{P}_{θ} and $\mathbb{P}_{\theta'}$ is a simple function of the densities f_{θ} and $f_{\theta'}$:

$$\mathsf{TV}(\mathbb{P}_{\theta}, \mathbb{P}_{\theta'}) = \frac{1}{2} \int_{E} |f_{\theta}(x) - f_{\theta'}(x)| dx.$$

Properties of Total variation

```
 \begin{array}{ll} & \mathsf{TV}(\mathbb{P}_{\theta},\mathbb{P}_{\theta'}) = \mathsf{TV}(\mathbb{P}_{\theta'},\mathbb{P}_{\theta}) & \mathsf{(symmetric)} \\ & \mathsf{TV}(\mathbb{P}_{\theta},\mathbb{P}_{\theta'}) \geq 0 & \mathsf{(positive)} \\ & \mathsf{If}\; \mathsf{TV}(\mathbb{P}_{\theta},\mathbb{P}_{\theta'}) = 0 \; \mathsf{then}\; \mathbb{P}_{\theta} = \mathbb{P}_{\theta'} & \mathsf{(definite)} \\ & \mathsf{TV}(\mathbb{P}_{\theta},\mathbb{P}_{\theta'}) \leq & \mathsf{(triangle inequality)} \end{array}
```

These imply that the total variation is a *distance* between probability distributions.

Exercises

Compute:

$$\mathbf{a)}\mathsf{TV}(\mathsf{Ber}(0.5),\mathsf{Ber}(0.1)) =$$

$$\textbf{b)} \; \mathsf{TV}(\mathsf{Ber}(0.5), \mathsf{Ber}(0.9)) =$$

$$\textbf{c)}\mathsf{TV}(\mathsf{Exp}(1),\mathsf{Unif}[0,1]) =$$

d)
$$\mathrm{TV}(X,X+a) =$$
 for any $a \in (0,1)$, where $X \sim \mathrm{Ber}(0.5)$

$$\label{eq:power_power} \begin{split} \mathbf{e)} \mathsf{TV}(2\sqrt{n}(\bar{X}_n-1/2),Z) = \\ \text{where } X_i \overset{i.i.d}{\sim} \mathsf{Ber}(0.5) \text{ and } Z \sim \mathcal{N}(0,1) \end{split}$$

An estimation strategy

Build an estimator $\widehat{\mathsf{TV}}(\mathbb{P}_{\theta}, \mathbb{P}_{\theta^*})$ for all $\theta \in \Theta$. Then find $\hat{\theta}$ that minimizes the function $\theta \mapsto \widehat{\mathsf{TV}}(\mathbb{P}_{\theta}, \mathbb{P}_{\theta^*})$.

problem: Unclear how to build $\widehat{\mathsf{TV}}(\mathbb{P}_{\theta}, \mathbb{P}_{\theta^*})!$

Kullback-Leibler (KL) divergence

There are **many** distances between probability measures to replace total variation. Let us choose one that is more convenient.

Definition

The Kullback-Leibler¹ (KL) divergence between two probability measures \mathbb{P}_{θ} and $\mathbb{P}_{\theta'}$ is defined by

$$\mathsf{KL}(\mathbb{P}_{\theta}, \mathbb{P}_{\theta'}) = \left\{ \begin{array}{ll} \displaystyle \sum_{x \in E} p_{\theta}(x) \log \left(\frac{p_{\theta}(x)}{p_{\theta'}(x)}\right) & \text{if E is discrete} \\ \\ \displaystyle \int_{E} f_{\theta}(x) \log \left(\frac{f_{\theta}(x)}{f_{\theta'}(x)}\right) \! dx & \text{if E is continuous} \end{array} \right.$$

¹KL-divergence is also know as "relative entropy"

Properties of KL-divergence

- $ightharpoonup \mathsf{KL}(\mathbb{P}_{\theta},\mathbb{P}_{\theta'})
 eq \mathsf{KL}(\mathbb{P}_{\theta'},\mathbb{P}_{\theta})$ in general
- $ightharpoonup \mathsf{KL}(\mathbb{P}_{\theta},\mathbb{P}_{\theta'}) \geq 0$
- ▶ If $\mathsf{KL}(\mathbb{P}_{\theta}, \mathbb{P}_{\theta'}) = 0$ then $\mathbb{P}_{\theta} = \mathbb{P}_{\theta'}$ (definite)
- $\blacktriangleright \ \mathsf{KL}(\mathbb{P}_{\theta},\mathbb{P}_{\theta'}) \nleq \mathsf{KL}(\mathbb{P}_{\theta},\mathbb{P}_{\theta''}) + \mathsf{KL}(\mathbb{P}_{\theta''},\mathbb{P}_{\theta'}) \ \mathsf{in} \ \mathsf{general}$

Not a distance.

This is is called a divergence.

Asymmetry is the key to our ability to estimate it!

Maximum likelihood estimation

Estimating the KL

$$\begin{aligned} \mathsf{KL}(\mathbb{P}_{\theta^*}, \mathbb{P}_{\theta}) &= \mathbb{E}_{\theta^*} \Big[\log \Big(\frac{p_{\theta^*}(X)}{p_{\theta}(X)} \Big) \Big] \\ &= \mathbb{E}_{\theta^*} \Big[\log p_{\theta^*}(X) \Big] - \mathbb{E}_{\theta^*} \Big[\log p_{\theta}(X) \Big] \end{aligned}$$

So the function $\theta \mapsto \mathsf{KL}(\mathbb{P}_{\theta^*}, \mathbb{P}_{\theta})$ is of the form:

"constant"
$$-\mathbb{E}_{\theta^*}\big[\log p_{\theta}(X)\big]$$

Can be estimated: $\mathbb{E}_{\theta^*}[h(X)] \leadsto \frac{1}{n} \sum_{i=1}^n h(X_i)$ (by LLN)

$$\widehat{\mathsf{KL}}(\mathbb{P}_{\theta^*}, \mathbb{P}_{\theta}) = \text{``constant''} - \frac{1}{n} \sum_{i=1}^n \log p_{\theta}(X_i)$$

Maximum likelihood

$$\widehat{\mathsf{KL}}(\mathbb{P}_{\theta^*}, \mathbb{P}_{\theta}) = \text{``constant''} - \frac{1}{n} \sum_{i=1}^n \log p_{\theta}(X_i)$$

$$\begin{split} \min_{\theta \in \Theta} \widehat{\mathsf{KL}}(\mathbb{P}_{\theta^*}, \mathbb{P}_{\theta}) & \Leftrightarrow & \min_{\theta \in \Theta} -\frac{1}{n} \sum_{i=1}^n \log p_{\theta}(X_i) \\ & \Leftrightarrow & \max_{\theta \in \Theta} \frac{1}{n} \sum_{i=1}^n \log p_{\theta}(X_i) \\ & \Leftrightarrow & \max_{\theta \in \Theta} \sum_{i=1}^n \log p_{\theta}(X_i) \\ & \Leftrightarrow & \max_{\theta \in \Theta} \prod_{i=1}^n p_{\theta}(X_i) \end{split}$$

This is the maximum likelihood principle.

Likelihood, Discrete case (1)

Let $(E, (\mathbb{P}_{\theta})_{\theta \in \Theta})$ be a statistical model associated with a sample of i.i.d. r.v. X_1, \ldots, X_n . Assume that E is discrete (i.e., finite or countable).

Definition

The *likelihood* of the model is the map L_n (or just L) defined as:

$$L_n: E^n \times \Theta \to \mathbb{R}$$

 $(x_1, \dots, x_n, \theta) \mapsto \mathbb{P}_{\theta}[X_1 = x_1, \dots, X_n = x_n].$

Likelihood for the Bernoulli model

Example 1 (Bernoulli trials): If $X_1, \ldots, X_n \stackrel{iid}{\sim} \mathrm{Ber}(p)$ for some $p \in (0,1)$:

- $E = \{0, 1\};$
- ▶ $\Theta = (0,1);$
- $\forall (x_1, \dots, x_n) \in \{0, 1\}^n, \forall p \in (0, 1),$

$$L(x_1, ..., x_n, p) = \prod_{i=1}^n \mathbb{P}_p[X_i = x_i]$$

$$= \prod_{i=1}^n p^{x_i} (1-p)^{1-x_i}$$

$$= p^{\sum_{i=1}^n x_i} (1-p)^{n-\sum_{i=1}^n x_i}.$$

Likelihood for the Poisson model

Example 2 (Poisson model):

If $X_1, \ldots, X_n \stackrel{iid}{\sim} \mathsf{Poiss}(\lambda)$ for some $\lambda > 0$:

- $ightharpoonup E = \mathbb{N};$
- $\bullet \ \Theta = (0, \infty);$
- $\forall (x_1,\ldots,x_n) \in \mathbb{N}^n, \forall \lambda > 0,$

$$L(x_1, \dots, x_n, p) = e^{-n\lambda} \frac{\lambda^{\sum_{i=1}^n x_i}}{x_1! \dots x_n!}.$$

Likelihood, Continuous case

Let $(E, (\mathbb{P}_{\theta})_{\theta \in \Theta})$ be a statistical model associated with a sample of i.i.d. r.v. X_1, \ldots, X_n . Assume that all the \mathbb{P}_{θ} have density f_{θ} .

Definition

The *likelihood* of the model is the map L defined as:

$$L: E^n \times \Theta \to \mathbb{R}$$

 $(x_1, \dots, x_n, \theta) \mapsto \prod_{i=1}^n f_{\theta}(x_i).$

Likelihood for the Gaussian model

Example 1 (Gaussian model): If $X_1, \ldots, X_n \stackrel{iid}{\sim} \mathcal{N}(\mu, \sigma^2)$, for some $\mu \in \mathbb{R}, \sigma^2 > 0$:

- $ightharpoonup E = \mathbb{R};$
- $\Theta = \mathbb{R} \times (0, \infty)$
- $\forall (x_1,\ldots,x_n) \in \mathbb{R}^n, \ \forall (\mu,\sigma^2) \in \mathbb{R} \times (0,\infty),$

$$L(x_1, ..., x_n, \mu, \sigma^2) = \frac{1}{(\sigma\sqrt{2\pi})^n} \exp\left(-\frac{1}{2\sigma^2} \sum_{i=1}^n (x_i - \mu)^2\right).$$

Exercises

Let $(E, (\mathbb{P}_{\theta})_{\theta \in \Theta})$ be a statistical model associated with $X_1, \dots, X_n \sim \mathsf{Exp}(\lambda)$.

a) What is E?

b) What is Θ ?

c) Find the likelihood of the model.

Exercise

Let $\left(E,(\mathbb{P}_{\theta})_{\theta\in\Theta}\right)$ be a statistical model associated with $X_1,\ldots,X_n{\sim}\mathsf{Unif}[0,b]$ for some b>0.

a) What is E?

b) What is Θ ?

c) Find the likelihood of the model.

Maximum likelihood estimator

Let X_1,\ldots,X_n be an i.i.d. sample associated with a statistical model $\left(E,(\mathbb{P}_{\theta})_{\theta\in\Theta}\right)$ and let L be the corresponding likelihood.

Definition

The maximum likelihood estimator of θ is defined as:

$$\hat{\theta}_n^{MLE} = \underset{\theta \in \Theta}{\operatorname{argmax}} L(X_1, \dots, X_n, \theta),$$

provided it exists.

Remark (log-likelihood estimator): In practice, we use the fact that

$$\hat{\theta}_n^{MLE} = \underset{\theta \in \Theta}{\operatorname{argmax}} \log L(X_1, \dots, X_n, \theta).$$

Interlude: maximizing/minimizing functions

Note that

$$\min_{\theta \in \Theta} -h(\theta) \quad \Leftrightarrow \quad \max_{\theta \in \Theta} h(\theta)$$

In this class, we focus on maximization.

Maximization of arbitrary functions can be difficult:

Example: $\theta \mapsto \prod_{i=1}^n (\theta - X_i)$

Concave and convex functions

Definition

A function twice differentiable function $h:\Theta\subset\mathbb{R}\to\mathbb{R}$ is said to be *concave* if its second derivative satisfies

$$h''(\theta) \le 0$$
, $\forall \theta \in \Theta$

It is said to be *strictly concave* if the inequality is strict: $h''(\theta) < 0$

Moreover, h is said to be (strictly) *convex* if -h is (strictly) concave, i.e. $h''(\theta) \ge 0$ ($h''(\theta) > 0$).

Examples:

- $\Theta = \mathbb{R}, \ h(\theta) = -\theta^2,$
- $\Theta = (0, \infty), \ h(\theta) = \sqrt{\theta},$
- $\Theta = (0, \infty), h(\theta) = \log \theta,$
- $\Theta = [0, \pi], \ h(\theta) = \sin(\theta)$
- $\Theta = \mathbb{R}, h(\theta) = 2\theta 3$

Multivariate concave functions

More generally for a *multivariate* function: $h:\Theta\subset \mathbb{R}^d \to \mathbb{R}$, $d \geq 2$, define the

$$\qquad \qquad \textbf{\textit{gradient vector: }} \nabla h(\theta) = \left(\begin{array}{c} \frac{\partial h}{\partial \theta_1}(\theta) \\ \vdots \\ \frac{\partial h}{\partial \theta_d}(\theta) \end{array} \right) \in {\rm I\!R}^d$$

$$\textbf{Hessian matrix:} \\ \mathbf{H}h(\theta) = \begin{pmatrix} \frac{\partial^2 h}{\partial \theta_1 \partial \theta_1}(\theta) & \cdots & \frac{\partial^2 h}{\partial \theta_1 \partial \theta_d}(\theta) \\ \\ \frac{\partial^2 h}{\partial \theta_d \partial \theta_d}(\theta) & \cdots & \frac{\partial^2 h}{\partial \theta_d \partial \theta_d}(\theta) \end{pmatrix} \in \mathbb{R}^{d \times d}$$

h is concave $\Leftrightarrow x^{\top}\mathbf{H}h(\theta)x \leq 0 \quad \forall x \in \mathbb{R}^d, \ \theta \in \Theta.$

h is strictly concave \Leftrightarrow $x^{\top}\mathbf{H}h(\theta)x < 0 \quad \forall x \in \mathbb{R}^d, \ \theta \in \Theta.$

Examples:

$$\Theta = \mathbb{R}^2$$
, $h(\theta) = -\theta_1^2 - 2\theta_2^2$ or $h(\theta) = -(\theta_1 - \theta_2)^2$

$$\Theta = (0, \infty), h(\theta) = \log(\theta_1 + \theta_2),$$

Optimality conditions

Strictly concave functions are easy to maximize: if they have a maximum, then it is **unique**. It is the unique solution to

$$h'(\theta) = 0\,,$$

or, in the multivariate case

$$\nabla h(\theta) = 0 \in \mathbb{R}^d$$
.

There are many algorithms to find it numerically: this is the theory of "convex optimization". In this class, often a **closed form formula** for the maximum.

Exercises

- a) Which one of the following functions are concave on $\Theta = \mathbb{R}^2$?
 - 1. $h(\theta) = -(\theta_1 \theta_2)^2 \theta_1 \theta_2$
 - 2. $h(\theta) = -(\theta_1 \theta_2)^2 + \theta_1 \theta_2$
 - 3. $h(\theta) = (\theta_1 \theta_2)^2 \theta_1 \theta_2$
 - 4. Both 1. and 2.
 - 5. All of the above
 - 6. None of the above
- **b)**Let $h:\Theta\subset\mathbb{R}^d\to\mathbb{R}$ be a function whose hessian matrix $\mathbf{H}h(\theta)$ has a positive diagonal entry for some $\theta\in\Theta$. Can h be concave? Why or why not?

Examples of maximum likelihood estimators

- ▶ Bernoulli trials: $\hat{p}_n^{MLE} = \bar{X}_n$.
- Poisson model: $\hat{\lambda}_n^{MLE} = \bar{X}_n$.
- ▶ Gaussian model: $(\hat{\mu}_n, \hat{\sigma}_n^2) = (\bar{X}_n, \hat{S}_n)$.

Consistency of maximum likelihood estimator

Under mild regularity conditions, we have

$$\hat{\theta}_n^{MLE} \xrightarrow[n \to \infty]{\mathbb{P}} \theta^*$$

This is because for all $\theta \in \Theta$

$$\frac{1}{n}L(X_1,\ldots,X_n,\theta) \xrightarrow[n\to\infty]{\mathbb{P}} \text{"constant"} - \mathsf{KL}(\mathbb{P}_{\theta^*},\mathbb{P}_{\theta})$$

Moreover, the minimizer of the right-hand side is θ^* if the parameter is identifiable.

Technical conditions allow to transfer this convergence to the minimizers.

Covariance

How about asymptotic normality?

In general, when $\theta\subset{\rm I\!R}^d, d\geq 2$, its coordinates are not necessarily independent.

The **covariance** between two random variables X and Y is

$$\begin{aligned} \mathsf{Cov}(X,Y) &= \mathbb{E} \big[\big(X - \mathbb{E}(X) \big) \cdot \big(Y - \mathbb{E}(Y) \big) \big] \\ &= \mathbb{E} \big[X \cdot Y \big] - \mathbb{E}[X] \mathbb{E}[Y] \\ &= \mathbb{E} \big[X \cdot \big(Y - \mathbb{E}(Y) \big) \big] \end{aligned}$$

Properties

- $ightharpoonup \operatorname{Cov}(X,Y) = \operatorname{Var}(X)$
- $ightharpoonup \mathsf{Cov}(X,Y) = \mathsf{Cov}(Y,X)$
- ▶ If X and Y are independent, then Cov(X,Y) = 0

In general, the **converse is not true** except if $(X,Y)^{\top}$ is a **Gaussian vector**², i.e., $\alpha X + \beta Y$ is Gaussian for all $(\alpha,\beta) \in \mathbb{R}^{\setminus}\{(0,0)\}.$

Take
$$X\sim \mathcal{N}(0,1),\ B\sim \mathrm{Ber}(1/2),\ R=2B-1\sim \mathrm{Rad}(1/2).$$
 Then
$$Y=R\cdot X\sim \mathcal{N}(0,1)$$

But taking $\alpha = \beta = 1$, we get

$$X + Y = \begin{cases} 0 & \text{with prob. } 1/2 \\ 2X & \text{with prob. } 1/2 \end{cases}$$

Actually Cov(X,Y) = 0 but they are not independent: |X| = |Y|

Covariance matrix

The covariance matrix of a random vector $X = (X^{(1)}, \dots, X^{(d)})^{\top} \in \rm I\!R^d$ is given by

$$\Sigma = \mathbf{Cov}(X) = \mathbb{E}[(X - \mathbb{E}(X))(X - \mathbb{E}(X))^{\top}]$$

This is a matrix of size $d \times d$.

The term on the ith row and jth column is

$$\Sigma_{ij} = \mathbb{E}\left[\left(X^{(i)} - \mathbb{E}(X^{(i)})\right)\left(X^{(j)} - \mathbb{E}(X^{(j)})\right)\right] = \mathsf{Cov}(X^{(i)}, X^{(j)})$$

In particular, on the diagonal, we have $\Sigma_{ii} = \operatorname{Cov}(X^{(i)}, X^{(i)}) = \operatorname{Var}(X^{(i)})$

Recall that for $X \in \mathbb{R}$, $Var(aX + b) = a^2Var(X)$. Actually, if $X \in \mathbb{R}^d$ and A, B are matrices:

$$Cov(AX + B) = A\Sigma A^{\top}$$

The multivariate Gaussian distribution

If $(X,Y)^{\top}$ is a Gaussian vector then its pdf depends on 5 parameters:

$$\mathop{\mathrm{I\!E}}[X], \ \mathop{\mathrm{I\!E}}[Y], \ \mathsf{Var}(X), \ \mathsf{Var}(Y) \quad \text{and} \quad \mathsf{Cov}(X,Y)$$

More generally, a Gaussian vector³ $X \in \mathbb{R}^d$, is completely determined by its expected value and $\mathbb{E}[X] = \mu \in \mathbb{R}^d$ covariance matrix Σ . We write

$$X \sim \mathcal{N}_d(\mu, \Sigma)$$
.

It has pdf over \mathbb{R}^d given by:

$$\frac{1}{(2\pi \det(\Sigma))^{d/2}} \exp\left(-\frac{1}{2}(x-\mu)^{\top} \Sigma^{-1}(x-\mu)\right)$$

³As before, this means that $\alpha^{\top}X$ is Gaussian for any $\alpha \in \mathbb{R}^d, \alpha \neq 0$.

The multivariate CLT

The CLT may be generalized to averages or random vectors (also vectors of averages).

Let $X_1,\ldots,X_n\in {\rm I\!R}^d$ be independent copies of a random vector X such that ${\rm I\!E}[X]=\mu$, ${\rm Cov}(X)=\Sigma$,

$$\sqrt{n}(\bar{X}_n - \mu) \xrightarrow[n \to \infty]{(d)} \mathcal{N}_d(0, \Sigma)$$

Equivalently

$$\sqrt{n}\Sigma^{-1/2}(\bar{X}_n - \mu) \xrightarrow[n \to \infty]{(d)} \mathcal{N}_d(0, I_d)$$

Multivariate Delta method

Let $(T_n)_{n\geq 1}$ sequence of random vectors in \mathbb{R}^d such that

$$\sqrt{n}(T_n - \theta) \xrightarrow[n \to \infty]{(d)} \mathcal{N}_d(0, \Sigma),$$

for some $\theta \in \mathbb{R}^d$ and some covariance $\Sigma \in \mathbb{R}^{d \times d}$.

Let $g: \mathbb{R}^d \to \mathbb{R}^k$ $(k \ge 1)$ be continuously differentiable at θ . Then,

$$\sqrt{n} \left(g(T_n) - g(\theta) \right) \xrightarrow[n \to \infty]{(d)} \mathcal{N}_k \left(0, \nabla g(\theta)^\top \Sigma \nabla g(\theta) \right),$$

where
$$\nabla g(\theta) = \frac{\partial g}{\partial \theta}(\theta) = \left(\frac{\partial g_j}{\partial \theta_i}\right)_{\substack{1 \leq i \leq d \\ 1 \leq j \leq k}} \in \mathbb{R}^{d \times k}.$$

Fisher Information

Definition: Fisher information

Define the log-likelihood for one observation as:

$$\ell(\theta) = \log L_1(X, \theta), \quad \theta \in \Theta \subset \mathbb{R}^d$$

Assume that ℓ is a.s. twice differentiable. Under some regularity conditions, the *Fisher information* of the statistical model is defined as:

$$I(\theta) = \mathbb{E} \left[\nabla \ell(\theta) \nabla \ell(\theta)^{\top} \right] - \mathbb{E} \left[\nabla \ell(\theta) \right] \mathbb{E} \left[\nabla \ell(\theta) \right]^{\top} = - \mathbb{E} \left[\mathbf{H} \ell(\theta) \right].$$

If $\Theta \subset \mathbb{R}$, we get:

$$I(\theta) = \operatorname{var}[\ell'(\theta)] = -\operatorname{I\!E}[\ell''(\theta)]$$

Fisher information of the Bernoulli experiment

Let $X \sim \mathsf{Ber}(p)$.

$$\ell(p) = \log(p^X(1-p)^{(1-X)}) = X\log p + (1-X)\log(1-p)$$

$$\ell'(p) = \frac{X}{p} - \frac{1-X}{1-p} \qquad \operatorname{var}[\ell'(p)] = \frac{1}{p(1-p)}$$

$$\ell''(p) = -\frac{X}{p^2} - \frac{1-X}{(1-p)^2} - \mathbb{E}[\ell''(p)] = \frac{1}{p(1-p)}$$

Asymptotic normality of the MLE

Theorem

Let $\theta^* \in \Theta$ (the *true* parameter). Assume the following:

- 1. The parameter is identifiable.
- 2. For all $\theta \in \Theta$, the support of \mathbb{P}_{θ} does not depend on θ ;
- 3. θ^* is not on the boundary of Θ ;
- **4**. $I(\theta)$ is invertible in a neighborhood of θ^* ;
- 5. A few more technical conditions.

Then, $\hat{\theta}_n^{MLE}$ satisfies:

$$\qquad \qquad \sqrt{n} \left(\hat{\theta}_n^{MLE} - \theta^* \right) \xrightarrow[n \to \infty]{(d)} \mathcal{N} \left(0, I(\theta^*)^{-1} \right) \qquad \text{w.r.t. } \mathbb{P}_{\theta^*}.$$

The method of moments

Moments

Let X_1,\dots,X_n be an i.i.d. sample associated with a statistical model $\left(E,(\mathbb{P}_\theta)_{\theta\in\Theta}\right)$.

- ▶ Assume that $E \subseteq \mathbb{R}$ and $\Theta \subseteq \mathbb{R}^d$, for some $d \ge 1$.
- ▶ Population moments: Let $m_k(\theta) = \mathbb{E}_{\theta}[X_1^k], 1 \leq k \leq d.$
- ▶ Empirical moments: Let $\hat{m}_k = \overline{X_n^k} = \frac{1}{n} \sum_{i=1}^n X_i^k$, $1 \le k \le d$.
- ightharpoonup From LLN, for all k

$$\hat{m}_k \xrightarrow[n \to \infty]{\mathbb{P}/a.s} m_k(\theta)$$

More compactly, we say that the whole vector converges:

$$(\hat{m}_1, \dots, \hat{m}_d) \xrightarrow[n \to \infty]{\mathbb{P}/a.s} (m_1(\theta), \dots, m_d(\theta))$$

Moments estimator

Let

$$M: \Theta \to \mathbb{R}^d$$

 $\theta \mapsto M(\theta) = (m_1(\theta), \dots, m_d(\theta)).$

Assume M is one to one:

$$\theta = M^{-1}(m_1(\theta), \dots, m_d(\theta)).$$

Definition

Moments estimator of θ :

$$\hat{\theta}_n^{MM} = M^{-1}(\hat{m}_1, \dots, \hat{m}_d),$$

provided it exists.

Statistical analysis

- ▶ Recall $M(\theta) = (m_1(\theta), \dots, m_d(\theta));$
- $\blacktriangleright \text{ Let } \hat{M} = (\hat{m}_1, \dots, \hat{m}_d).$
- Let $\Sigma(\theta) = \operatorname{Cov}_{\theta}(X_1, X_1^2, \dots, X_1^d)$ be the covariance matrix of the random vector $(X_1, X_1^2, \dots, X_1^d)$, which we assume to exist.
- ▶ Assume M^{-1} is continuously differentiable at $M(\theta)$.

Method of moments (5)

Remark: The method of moments can be extended to more general moments, even when $E \not\subset {\rm I\!R}.$

- ▶ Let $g_1, \ldots, g_d : E \to \mathbb{R}$ be given functions, chosen by the practitioner.
- ightharpoonup Previously, $g_k(x)=x^k$, $x\in E=\mathbb{R}$, for all $k=1,\ldots,d$.
- ▶ Define $m_k(\theta) = \mathbb{E}_{\theta}[g_k(X)]$, for all k = 1, ..., d.
- Let $\Sigma(\theta) = \operatorname{Cov}_{\theta}(g_1(X_1), g_2(X_1), \dots, g_d(X_1))$ be the covariance matrix of the random vector $(g_1(X_1), g_2(X_1), \dots, g_d(X_1))$, which we assume to exist.
- Assume M is one to one and M^{-1} is continuously differentiable at $M(\theta)$.

Generalized method of moments

Applying the multivariate CLT and Delta method yields:

Theorem

$$\sqrt{n} \left(\hat{\theta}_n^{MM} - \theta \right) \xrightarrow[n \to \infty]{(d)} \mathcal{N} \left(0, \Gamma(\theta) \right) \quad \text{ (w.r.t. } \mathbb{P}_{\theta}),$$

where
$$\Gamma(\theta) = \left[\frac{\partial M^{-1}}{\partial \theta} \left(M(\theta)\right)\right]^{\top} \Sigma(\theta) \left[\frac{\partial M^{-1}}{\partial \theta} \left(M(\theta)\right)\right].$$

MLE vs. Moment estimator

Comparison of the quadratic risks: In general, the MLE is more accurate.

MLE still gives good results if model is misspecified

 Computational issues: Sometimes, the MLE is intractable but MM is easier (polynomial equations)

M-estimation

M-estimators

Idea:

- Let X_1, \ldots, X_n be i.i.d with some unknown distribution \mathbb{P} in some sample space E ($E \subseteq \mathbb{R}^d$ for some $d \ge 1$).
- ▶ No statistical model needs to be assumed (similar to ML).
- ▶ Goal: estimate some parameter μ^* associated with ${\rm I\!P}$, e.g. its mean, variance, median, other quantiles, the true parameter in some statistical model...
- ▶ Find a function $\rho: E \times \mathcal{M} \to \mathbb{R}$, where \mathcal{M} is the set of all possible values for the unknown μ^* , such that:

$$Q(\mu) := \mathbb{E}\left[\rho(X_1, \mu)\right]$$

achieves its minimum at $\mu = \mu^*$.

Examples (1)

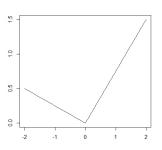

- If $E=\mathcal{M}=\mathbbm{R}$ and $\rho(x,\mu)=(x-\mu)^2$, for all $x\in\mathbbm{R},\mu\in\mathbbm{R}$: $\mu^*=$
- If $E = \mathcal{M} = \mathbb{R}^d$ and $\rho(x,\mu) = \|x \mu\|_2^2$, for all $x \in \mathbb{R}^d$, $\mu \in \mathbb{R}^d$: $\mu^* =$
- ▶ If $E = \mathcal{M} = \mathbb{R}$ and $\rho(x,\mu) = |x \mu|$, for all $x \in \mathbb{R}$, $\mu \in \mathbb{R}$: μ^* is a median of \mathbb{P} .

Examples (2)

If $E=\mathcal{M}=\mathbb{R}$, $\alpha\in(0,1)$ is fixed and $\rho(x,\mu)=C_{\alpha}(x-\mu)$, for all $x\in\mathbb{R},\mu\in\mathbb{R}$: μ^* is a α -quantile of \mathbb{P} .

Check function

$$C_{\alpha}(x) = \begin{cases} -(1-\alpha)x & \text{if } x < 0\\ \alpha x & \text{if } x \ge 0. \end{cases}$$

MLE is an M-estimator

Assume that $(E, \{\mathbb{I}\mathbb{P}_{\theta}\}_{\theta \in \Theta})$ is a statistical model associated with the data.

Theorem

Let $\mathcal{M}=\Theta$ and $\rho(x,\theta)=-\log L_1(x,\theta)$, provided the likelihood is positive everywhere. Then,

$$\mu^* = \theta^*,$$

where $\mathbb{P} = \mathbb{P}_{\theta^*}$ (i.e., θ^* is the true value of the parameter).

Definition

▶ Define $\hat{\mu}_n$ as a minimizer of:

$$Q_n(\mu) := \frac{1}{n} \sum_{i=1}^n \rho(X_i, \mu).$$

► Examples: Empirical mean, empirical median, empirical quantiles, MLE, etc.

Statistical analysis

Let $J(\mu) = \frac{\partial^2 Q}{\partial \mu \partial \mu^\top}(\mu)$ (= $\mathbb{E}\left[\frac{\partial^2 \rho}{\partial \mu \partial \mu^\top}(X_1, \mu)\right]$ under some regularity conditions).

Let
$$K(\mu) = \text{Cov}\left[\frac{\partial \rho}{\partial \mu}(X_1, \mu)\right].$$

Remark: In the log-likelihood case (write $\mu = \theta$),

$$J(\theta) = K(\theta) = I(\theta)$$
 Fisher Information

Asymptotic normality

Let $\mu^* \in \mathcal{M}$ (the *true* parameter). Assume the following:

- 1. μ^* is the only minimizer of the function Q;
- 2. $J(\mu)$ is invertible for all $\mu \in \mathcal{M}$;
- 3. A few more technical conditions.

Then, $\hat{\mu}_n$ satisfies:

M-estimators in robust statistics

Example: Location parameter

If X_1, \ldots, X_n are i.i.d. with density $f(\cdot - m)$, where:

- f is an unknown, positive, even function (e.g., the Cauchy density);
- m is a real number of interest, a location parameter;

How to estimate m?

- ▶ M-estimators: empirical mean, empirical median, ...
- Compare their risks or asymptotic variances;
- ▶ The empirical median is more *robust*.

Recap

- Three principled methods for estimation: maximum likelihood, Method of moments, M-estimators
- ▶ Maximum likelihood is an example of *M*-estimation
- Method of moments inverts the function that maps parameters to moments
- All methods yield to asymptotic normality under regularity conditions
- Asymptotic covariance matrix can be computed using multivariate Δ-method
- For MLE, asymptotic covariance matrix is the inverse Fisher information matrix
