### 3. Likelihood Ratio Test

In the problems on this page, we consider a sample  $X_1,\ldots,X_n \stackrel{iid}{\sim} \mathbf{ShiftExp}\,(\lambda,a)$ , where  $\mathbf{ShiftExp}\,(\lambda,a)$  is a continuous probability distribution with parameters  $\lambda>0, a\in\mathbb{R}$  and pdf

$$f_{\lambda,a}\left(x
ight)=\lambda e^{-\lambda\left(x-a
ight)}\mathbf{1}_{x\geq a}.$$

## Likelihood for Shifted Exponential

1/1得分 (计入成绩)

Which of the following is the likelihood function  $L\left(X_1,\ldots,X_n;\lambda,a\right)$  for the shifted exponential statistical model?

$$L(X_1,\ldots,X_n;\lambda,a)=$$

- $0 \lambda^n \exp\left(\lambda \sum_{i=1}^n \left(X_i a
  ight)\right) \mathbf{1}_{\min(X_i) \geq a}$
- $\lambda^n \exp\left(-\lambda \sum_{i=1}^n (X_i a)\right)$
- ullet  $\lambda^n \exp\left(-\lambda \sum_{i=1}^n \left(X_i a
  ight)\right) \mathbf{1}_{\min(X_i) \geq a} \ \Box$
- $\bigcirc \exp\left(-\lambda \sum_{i=1}^{n} (X_i a)\right) \mathbf{1}_{\min(X_i) \geq a}$

### Solution:

By definition, the likelihood is computed to be

$$egin{aligned} L\left(X_1,\ldots,X_n;\lambda,a
ight) &= \prod_{i=1}^n \lambda e^{-\lambda(X_i-a)} \mathbf{1}_{X_i \geq a} \ &= \lambda^n \exp\left(-\lambda \sum_{i=1}^n \left(X_i-a
ight)
ight) \mathbf{1}_{\min_{i=1,\ldots,n}(X_i) \geq a}. \end{aligned}$$

The third choice is correct.

# MLE for Shifted Exponential

2/2得分 (计入成绩)

Let  $(\hat{\lambda}, \hat{a})$  denote the MLE for the shifted exponential model.

What is  $\hat{a}$ ?

- $\circ \max_{i=1,\ldots,n} X_i$
- $lacksquare \min_{i=1,\ldots,n} X_i \ \Box$

 $-\min_{i=1,\ldots,n} X_i$ 

None of the above.

What is  $\hat{\lambda}$ ? Your answer should be expressed in terms of the sample mean  $\overline{X}_n$  and  $\hat{a}$ .

(Enter  $\operatorname{{f bar X}}_n$  for  $\overline{X_n}$  and  $\operatorname{{f hat a}}$  for  $\hat{a}$ .)

$$\hat{\lambda} = \begin{bmatrix} 1/(\text{barX_n - hata}) \end{bmatrix}$$
  $\Box$  Answer: 1/(barX\_n-hata)

**STANDARD NOTATION** 

#### **Solution:**

Observe that the likelihood L=0 if  $a>\min_i{(X_i)}$ , so let's restrict to  $a\leq\min_i{(X_i)}$ . Taking the log, then we need to maximize the function

$$\ell\left(\lambda,a
ight) := n \ln \lambda - \lambda \sum_{i=1}^{n} X_i + n \lambda a$$

with respect to  $\lambda$  and a.

Since  $\lambda > 0$ , we see that this function is monotone increasing in a, so we choose a to be as large as possible given the constraint  $a \leq \min_i (X_i)$ . Accordingly, we set

$$\hat{a} = \min_{i=1,\ldots,n} \left( X_i 
ight).$$

To compute  $\hat{\lambda}$ , we set  $a=\min_{i=1,\ldots,n}{(X_i)}$ , and need to maximize the function

$$f\left(\lambda
ight)=n\ln\lambda-\lambda\sum_{i=1}^{n}X_{i}+n\lambda\min_{i}\left(X_{i}
ight).$$

Observe that

$$f'\left(\lambda
ight) = rac{n}{\lambda} - \sum_{i=1}^{n} X_i + n \min_i \left(X_i
ight)$$

which is  $\mathbf{0}$  if we set

$$\lambda = rac{n}{\sum_{i=1}^{n}\left(X_{i}-\min_{j}\left(X_{j}
ight)
ight)} = rac{1}{\overline{X}_{n}-\hat{a}}.$$

Hence, we have

$$\hat{\lambda} = rac{1}{\overline{X}_n - \hat{a}}.$$

□ Answers are displayed within the problem
Likelihood Ratio Test for Shifted Exponential I
2/2得分 (计入成绩) While we cannot take the log of a negative number, it makes sense to define the log-likelihood of a shifted exponential to be

We will use this definition in the remaining problems.

Assume now that a is known and that a=0. Consider the hypotheses

$$H_0: \lambda = 1$$
 $H_1: \lambda \neq 1$ .

What is the likelihood-ratio test statistic  $T_n$ ?

(Enter  $\operatorname{{\sf barX}}_{-n}$  for  $\overline{X}_n$ .)

$$T_n = \begin{bmatrix} 2*n*(barX_n-1-ln(barX_n)) \end{bmatrix}$$
  $\Box$  Answer: 2\*(-n\*ln(barX\_n)-n+n\*barX\_n)

Assume that Wilks's theorem applies.

What is true about the distribution of  $T_n$ ?

- $igcup T_n$  is distributed as  $N\left(0,1
  ight)$ .
- $igcup T_n$  is asymptotically distributed as  $\chi_2^2$ .
- $\ \ \ \ \ T_n$  is distributed as  $\chi_1^2$ .
- $^ullet$   $T_n$  is asymptotically distributed as  $\chi_1^2$ .  $\Box$

#### **Solution:**

Since we are given that a=0 is known, we may write

$$\ell\left(\lambda,0
ight) = \left(n\ln\lambda - \lambda\sum_{i=1}^{n}\left(X_{i}
ight)
ight)\mathbf{1}_{\min_{i}\left(X_{i}
ight)\geq0} = n\ln\lambda - \lambda\sum_{i=1}^{n}\left(X_{i}
ight),$$

because the generated data will certainly satisfy  $\min_i (X_i) \geq 0$ .

The likelihood-ratio test statistic is

$$egin{aligned} T_n &= 2 \left( \ell \left( \hat{\lambda}, 0 
ight) - \ell \left( 1, 0 
ight) 
ight) \ &= 2 \left( n \ln \left( 1 / \overline{X}_n 
ight) - n - 0 + n \overline{X}_n 
ight) \ &= 2 \left( - n \ln \left( \overline{X}_n 
ight) - n + n \overline{X}_n 
ight). \end{aligned}$$

By Wilks's theorem,

$$T_n \stackrel{n o \infty}{\longrightarrow} \chi_1^2,$$

because the parameter  $\lambda$  is 1-dimensional.

## Likelihood Ratio Test for Shifted Exponential II

1/1得分 (计入成绩)

In this problem, we assume that  $\lambda=1$  and is known. The parameter  $a\in\mathbb{R}$  is now unknown.

As in the previous problem, you should use the following definition of the log-likelihood:

$$\ell\left(\lambda,a
ight) = \left(n\ln\lambda - \lambda\sum_{i=1}^n\left(X_i-a
ight)
ight)\mathbf{1}_{\min_i\left(X_i
ight)\geq a}.$$

Consider the following null and alternative hypotheses:

$$H_0: a \leq 1$$

$$H_1: a > 1.$$

Assuming that  $H_0$  holds, compute the test statistic  $\widetilde{T_n}$  for the log-likelihood ratio test for the above hypotheses.

(Enter **hata** for  $\hat{a}$ .)

$$\widetilde{T_n} = 2*n*(hata - 1)$$

☐ **Answer:** 2\*n\*(hata - 1)

STANDARD NOTATION

**Solution:** 

We compute that

$$egin{aligned} \widetilde{T_n} &= 2 \left( \ell \left( 1, \hat{a} 
ight) - \ell \left( 1, 1 
ight) 
ight) \ &= 2 \left( n \ln 1 - (1) \sum_{i=1}^n \left( X_i - \hat{a} 
ight) 
ight) \mathbf{1}_{\min_i(X_i) \geq \hat{a}} - 2 \left( n \ln 1 - (1) \sum_{i=1}^n \left( X_i - 1 
ight) 
ight) \mathbf{1}_{\min_i(X_i) \geq 1}. \end{aligned}$$

Recall that  $\hat{a}=\min_i{(X_i)}$ . Hence,  $\mathbf{1}_{\min_i{(X_i)}\geq\hat{a}}=1$ . Moreover, if  $H_0:a\leq 1$  holds, then  $\mathbf{1}_{\min_i{(X_i)}\geq 1}=1$ . We may further simplify

$$egin{align} \widetilde{T_n} &= 2\left(n\ln 1 - (1)\sum_{i=1}^n\left(X_i - \hat{a}
ight)
ight) - 2\left(n\ln 1 - (1)\sum_{i=1}^n\left(X_i - 1
ight)
ight) \ &= 2n\left(\hat{a} - 1
ight). \end{array}$$

### P-value for Likelihood Ratio Test for Shifted Exponential

1/2得分 (计入成绩)

What is the distribution of

$$\hat{a} = \min_{i=1,\ldots,n} \left( X_i 
ight)$$

assuming that a=1 and  $\lambda=1$ ?

- ullet ShiftExp (n,1)  $\Box$
- $\bigcirc$  ShiftExp (1,1)
- $\bigcirc$  ShiftExp (n, n)
- ShiftExp (1, -n)

Recall the test statistic  $\widetilde{T_n}$  from the previous question. Suppose that n=100 and  $\widetilde{T_{100}}=1.03$ .

What is the p-value associated to this observation?

0.995

☐ **Answer:** 0.5975

#### **Solution:**

We will compute the cdf of  $\hat{a} = \min_i{(X_i)}$ . Observe that by independence,

$$egin{aligned} P\left(\min_i\left(X_i
ight) \geq t
ight) &= \left(\int_t^\infty e^{-(x-1)} \ dx
ight)^n \ &= e^{-n(t-a)} \ &= \int_t^\infty -ne^{-n(x-1)} \ dx \ &= \int_t^\infty f_{n,1}\left(x
ight) \ dx. \end{aligned}$$

Therefore,  $\hat{\mathbf{a}} \sim \mathbf{ShiftExp}(\mathbf{n}, \mathbf{1})$ , if we assume that a = 1 and  $\lambda = 1$ .

For the second question, we use this result to compute the p-value:

$$egin{align} P\left(\widetilde{T_{100}}>1.03
ight) &= P\left(\hat{a}>1+rac{1.03}{200}
ight) \ &= \int_{1+rac{1.03}{200}}^{\infty} 100e^{-100(x-1)}\,dx \ &= e^{-1.03/2} \ &pprox 0.5975. \end{array}$$
