1. Revisiting MDP Fundamentals **Revisiting MDP Fundamentals**

Start of transcript. Skip to the end.

So today we will continue our discussion on reinforcement learning.

And it actually will be, for the first time we will have an algorithm which would enable you to solve reinforcement learning problems.

If you remember, last time we talked about Markov decision

processes.

So I will first start when I am talking about

0:00 / 0:00

Review: Markovian Assumption

1/1 point (graded)

Which of the following are true about Markov decision processes? (Choose all that apply.)

- \square The transition probability of reaching a state s' from a given state s would depend both on s and all the states visited before s
- lacktriangle The transition probability of reaching a state s' from a given state s would only depend on s and is independent of the states visited before state $s \checkmark$
- lacktriangle The rewards received starting from state s would depend both on s and all the states visited before s
- $m extbf{ extit{ extbf{ extit{ extit{\extit{\extit{\extit{ extit{ extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{ extit{ extit{ extit{ extit{\teit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\exti$

Solution:

Recall from the previous lecture that under Markovian assumptions, both the transition probability of reaching a state s' from a given state s, and the rewards received starting from state s, would only depend on s and is independent of the states visited before state s. This assumption allows us to specify the transition probabilities and rewards by T(s, a, s') and R(s, a, s').

Policy Function and Value Function

1/1 point (graded)

From the following options select one or more statement(s) which are true about the optimal policy function π^* , the optimal value function V^* and the optimal Q-function Q^*

- $riangleq \pi^*\left(s
 ight)$ records the action that would lead to the best expected utility starting from the state s
- $\pi^*(s)$ records the action that would necessarily lead to the best immediate reward for the current step
- $extbf{ extit{ extbf{ extit{ extbf{ extit{ extit{ extbf{ extit{ extit{ extbf{ extit{ extit{\extit{\extit{\extit{ extit{ extit{ extit{\extit{ extit{ extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{\extit{ extit{ extit{\tert{\extit{\$
- $extstyle V^*\left(s
 ight) = max_a\left[\sum_{s'}T\left(s,a,s'
 ight)\left(R\left(s,a,s'
 ight) + \gamma V^*\left(s'
 ight)
 ight)
 ight]$ must hold true for the optimal value function when $0<\gamma<1$ 🗸

Solution:

The goal of the optimal policy function is to maximize the expected discounted reward, even if this means taking actions that would lead to lower immediate next-step rewards from few states.

Recall that from the previous lecture that for all s, the (optimal) value function is

$$egin{aligned} V^*\left(s
ight) &=& \max_a Q^*\left(s,a
ight) \ &=& \max_a \left[\sum_{s'} T\left(s,a,s'
ight) \left(R\left(s,a,s'
ight) + \gamma V^*\left(s'
ight)
ight)
ight] \qquad ext{where } 0 \leq \gamma < 1. \end{aligned}$$
