7. Exercise: Sum of normals

Exercise: Sum of normals

3/3 points (graded)

Let \boldsymbol{X} and \boldsymbol{Y} be independent normal random variables.

a) Is 2X - 4 always normal?

b) Is 3X - 4Y always normal?

c) Is $oldsymbol{X^2 + Y}$ always normal?

Solution:

- a) This is a fact that we are already familiar with: a linear function of a normal random variable is normal.
- b) Since X and Y are independent and normal, the random variables $\mathbf{3}X$ and $-\mathbf{4}Y$ are also independent and normal. Since the sum of independent normals is normal, it follows that $\mathbf{3}X-\mathbf{4}Y$ is normal.
- c) There is no reason for this to be the case. To see this, consider an extreme case where Y=0 (a degenerate case of a normal). Then the random variable X^2+Y is nonnegative, which is incompatible with having a normal distribution.
